Muhammad Moiz Khan (2303.022.KHI.DEG)

ASSIGNMNET 1.2

Write a dataclass describing a mountain (containing fields for name and elevation) and:

- Construct an instance of the dataclass
- Convert it to string

CODE:

A screenshot of a Python IDE window titled 'abc_1.py - venv - V'. The window shows a file explorer on the left with a 'RUN' button and instructions. The main editor displays a Python script in 'abc_1.py' with the following code:

```
1 from dataclasses import dataclass
2
3 @dataclass
4 class Mountains:
5     name: str
6     elevation: int
7
8 mountains = Mountains(name="K2", elevation=8611)
9 print(str(mountains))
10
11
```

1. This code imports the "dataclass" module from the "dataclasses" library
2. The code above defines a Mountains class using the @dataclass decorator provided by the dataclasses module in Python.
3. Both attributes have specific data types, "str" and "int", respectively.
4. An instance of the Mountains class is then created with the name "K2" and the elevation 8611 meters.
5. Finally, the print() function is used to print the string representation of the mountains object using str(mountains) to the console.
6. This will output something like Mountains(name='K2', elevation=8611) indicating the values of the object's attributes.

OUTPUT:

```
